

Here is the background information on our task

PowerCo is a major gas and electricity utility that supplies to corporate, SME (Small & Medium Enterprise), and residential customers. The power-liberalization of the energy market in Europe has led to significant customer churn, especially in the SME segment. They have partnered with BCG to help diagnose the source of churning SME customers.

A fair hypothesis is that price changes affect customer churn. Therefore, it is helpful to know which customers are more (or less) likely to churn at their current price, for which a good predictive model could be useful.

Moreover, for those customers that are at risk of churning, a discount might incentivize them to stay with our client. It's being considered that a 20% discount is a large enough to dissuade almost anyone from churning (especially those for whom price is the primary concern).

During this overview, we discuss various hypotheses, including churn due to price sensitivity and go deeper on the hypothesis that the churn is driven by the customers' price sensitivities.

Your AD wants an email with your thoughts on how the team should go about testing this hypothesis.

The client plans to use the predictive model on the 1st working day of every month to indicate to which customers the 20% discount should be offered.
